## INTRODUCTION

Measurement of the serological response to SARS-CoV-2 immunization is necessary to establish a correlation between vaccination response and effective protective immunity. This study aimed to determine the SARS-CoV-2 antibody titres between male and female adolescents who received the BNT162b2 vaccine.

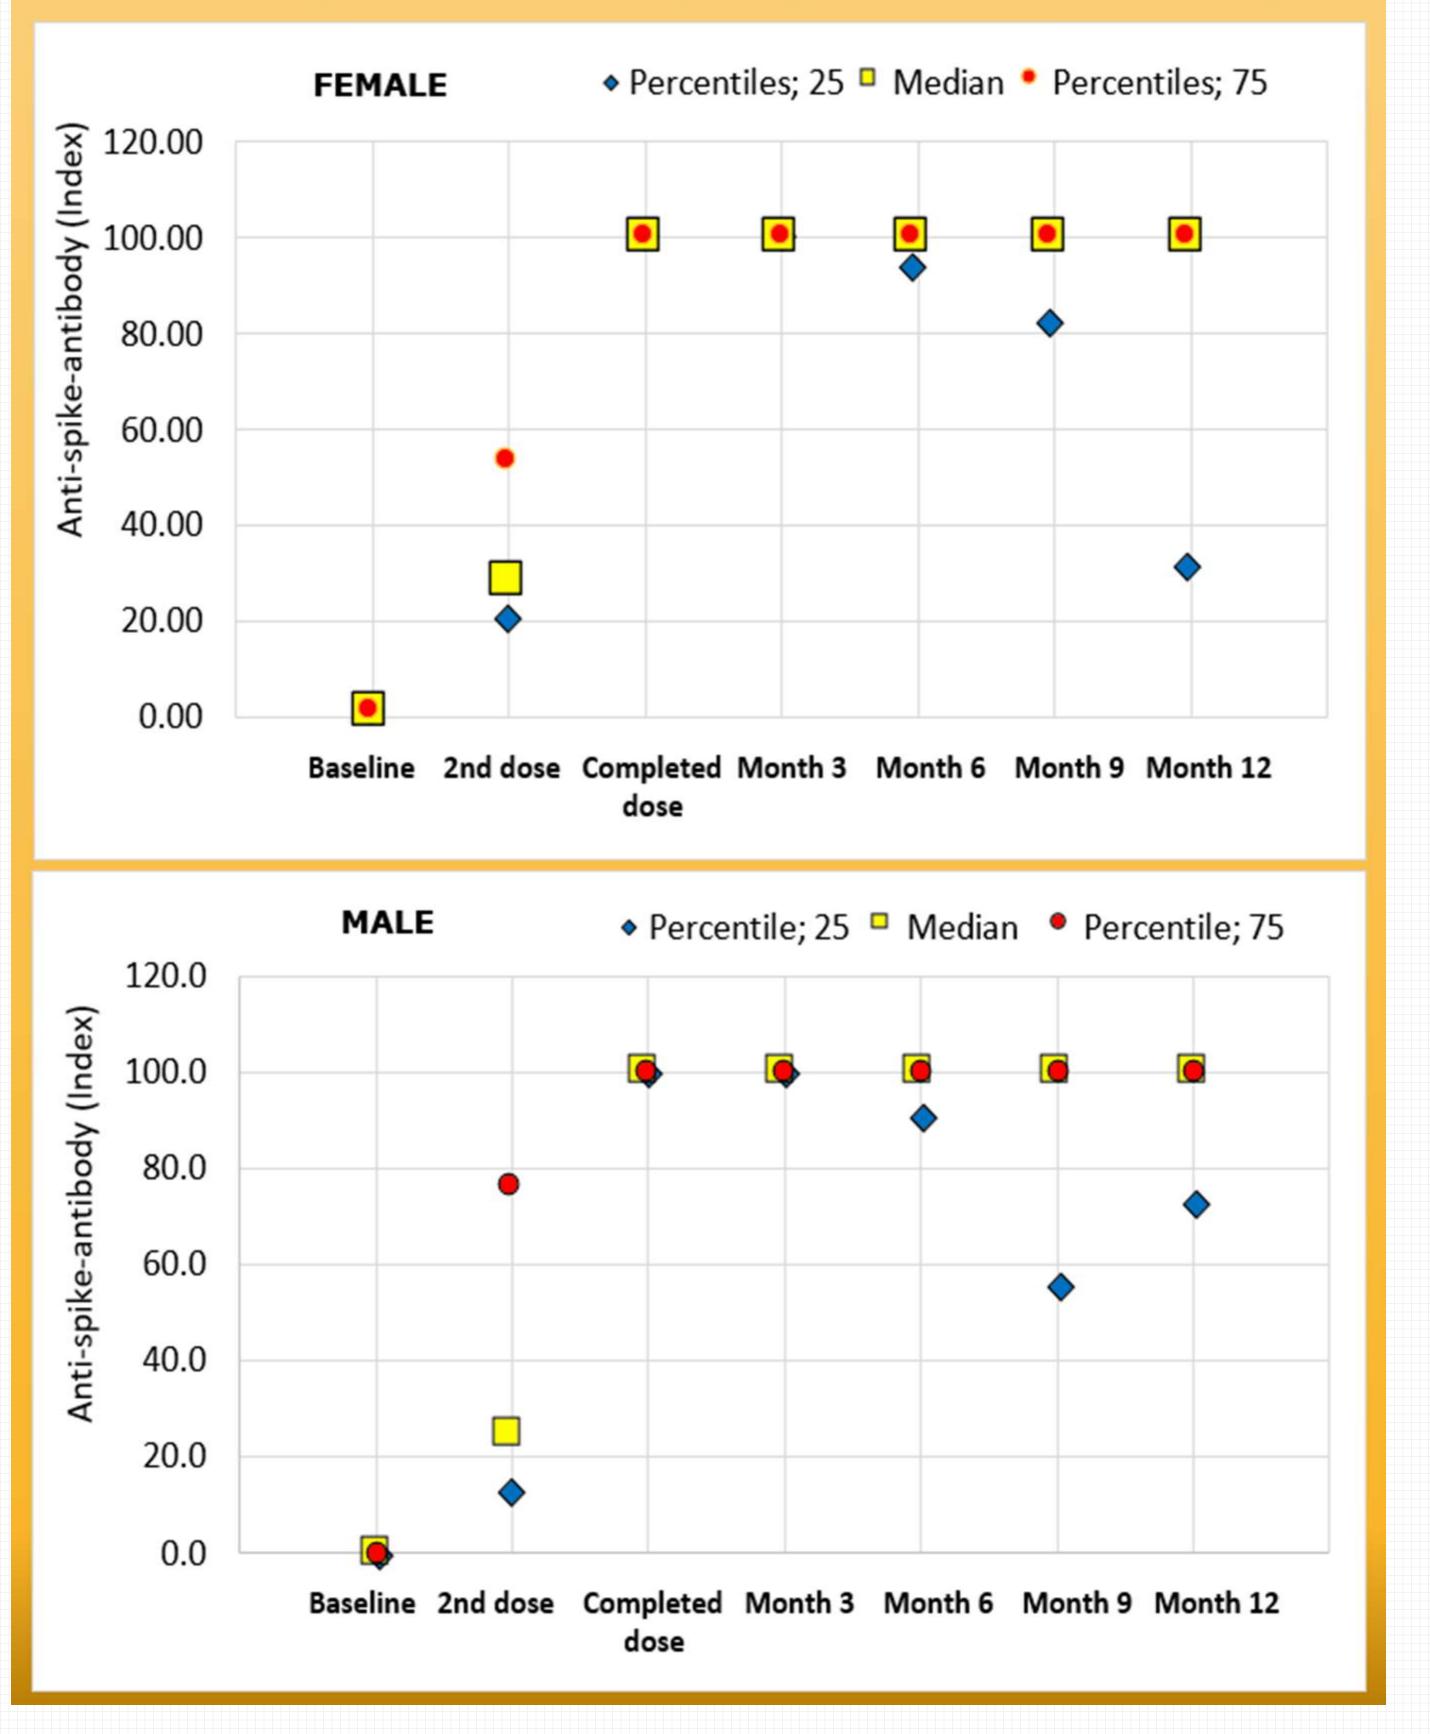

### METHODOLOGY

This was an observational cohort study. The participants were adolescents aged 12 to 17 years old who received the BNT162b2 vaccine for SARS-CoV-2 and had no previous history of COVID-19 infection. Blood samples were collected at seven different follow-up times. All blood samples were tested for SARS-CoV-2 anti-spike-IgG antibodies. Data was analysed using descriptive statistics and independent t-tests.

# RESULT

- ✓ Out of 153 participants, 96 were included with a mean age of 14.18 ± 1.71.
- ✓ 59.4% (n=57) were male and 40.6% (n=39) were female.
- ✓ The seropositive rate raised to 100% in both male and female at first dose follow-up and maintained until the end (12 months).
- ✓ Higher titres were seen in females [28.37 (20.27, 53.31] compared to male [24.71 (12.42, 77.23)] at first dose follow-up. However, the differences in titers index were small.
- ✓ The upper limit of detection from 25<sup>th</sup> percentile and above [100.0 (100.0, 100.0)] were reached at completed vaccination and at month 3 follow-up in both sexes showed the protective titers was very high for both sexes.

#### Seropositivity rate of SARS-CoV-2 IgG antibodies (Anti-spike-IgG) among adolescents by sex for BNT162b2 (Pfizer) vaccine based on follow up.

- ✓ At month 6 to month 12 follow-up showed a trend of decreasing antibodies titres at 25<sup>th</sup> percentile ending with 100.0 (72.26, 100.0) in male and 100.0 (30.78, 100.0) in female.
- ✓ However, there were no significant differences between the antibody titres and sex at first dose [t(84)=0.127, p=0.900], completed dose [t(73)=-0.099, p=0.922], month 3 [t(67)=0.668, p=0.506], month 6 [t(58)=-0.395, p=0.694], month 9 [t(52)=-0.682, p=0.498] and month 12 [t(35)=0.476, p=0.568] of follow-up.

### DISCUSSION

- Due to hormonal changes, it has been shown that there are sex variations in the immunological responses to adolescent immunisations; these sex-differential activities might become more apparent during puberty (1).
- Generally, testosterone has an immunosuppressive effect while estrogen has an immunoenhancing effect on the immune system (2).
- One of the reasons that may explain the sex bias in immune responses and a predominance of autoimmune disorders in women is gene diversity or dosage, which is many genes on X chromosome are associated with regulation of immune functions (2).
- There is limited evidence available about immunity following vaccination in adolescents. So, more research is needed in the future.

### CONCLUSION

Vaccination generates strong immune responses and remains an important way to provide adolescents' host protection against COVID-19.
